

ASYMPTOTIC RISK OF MAXIMUM
LIKELIHOOD ESTIMATES

1. Introduction.

The main result proved in this paper is a hypothesis conjectured by Chernoff (1956), that with increase in sample size, the risk, suitably normalized, of a maximum likelihood estimate (m.l.e.) converges to a limit equal to the variance of the asymptotic distribution of the estimate. The hypothesis is shown to hold generally subject to mild conditions. As the asymptotic variance is a lower bound for the risk function for all estimates, the result establishes a new optimum property of the m.l.e. viz that it is asymptotically of minimum risk.

Chernoff's above mentioned hypothesis has also been briefly referred to in a recent paper of Yu. V. Linnik and N. M. Mitrofanova (1965).

The efficiency of estimates in general is considered in the last section in connection with superefficient estimates and a revised definition of asymptotic efficiency suggested.

2. Main Result.

We first reproduce the relevant formulae from the above mentioned paper of Chernoff (1956). X is a random variable with a frequency function $f(x, \theta)$, with one unknown parameter θ . We consider a sequence of estimates of θ ,

$$T_n = T_n(X_1, X_2, \dots, X_n)$$

where

$$(1) \quad T_n - \theta = O_p\left(\frac{1}{\sqrt{n}}\right)$$

A sequence of loss functions is assumed, given by

$$(2) \quad L_n(t, \theta) = c_{0n}(\theta) + c_{2n}(t-\theta)^2$$

where $c_{2n} > 0$,

and of normalized loss functions,

$$(3) \quad L_n^*(t, \theta) = n \left[\frac{L_n(t, \theta) - c_{0n}(\theta)}{c_{2n}} \right]$$

where we assume,

$$(4) \quad L_n^*(t, \theta) = n[(t-\theta)^2 + \bullet(t-\theta)^2]$$

in which \bullet is assumed to hold uniformly in n as $t \rightarrow \theta$.

Then, c being an arbitrary constant > 0 ,

$$\liminf_{n \rightarrow \infty} \frac{E L_n^*(T_n, \theta)}{n E \{\min[(T_n - \theta)^2, \frac{c^2}{n}]\}} \geq 1$$

so that,

$$(5) \quad \lim_{c \rightarrow \infty} \liminf_{n \rightarrow \infty} \frac{E L_n^*(T_n, \theta)}{n E \{\min[(T_n - \theta)^2, \frac{c^2}{n}]\}} \geq 1$$

If $\sqrt{n} (T_n - \theta)$ has a limiting distribution with second moment $\sigma^2(\theta)$, then

$$(6) \quad \lim_{c \rightarrow \infty} \lim_{n \rightarrow \infty} n E \{\min[(T_n - \theta)^2, \frac{c^2}{n}]\} = \sigma^2(\theta)$$

so that $\sigma^2(\theta)$ is a lower bound for the risk function

$$(7) \quad R_n(T_n, \theta) = E \{L_n^*(T_n, \theta)\}$$

On the other hand if,

$$(8) \quad P\{|T_n - \theta| > c\} = \bullet \left(\frac{1}{n}\right)$$

for each c , it is possible to show that

$$(9) \quad \liminf_{n \rightarrow \infty} \frac{n E \{(T_n - \theta)^2\}}{E \{L_n^*(T_n, \theta)\}} \geq 1$$

so that the normalized risk is sandwiched between the real variance and the asymptotic variance.

Chernoff remarks that in accordance with the axioms of Neumann and Morgenstein the loss function requires to be bounded above and (8) indicates that he assumes an upper bound C for the loss function in (2) and hence an upper bound $n C$ for the normalized loss function in (3), so that

$$(10) \quad L_n^*(t, \theta) \leq n C$$

Chernoff's conjecture then is that if T_n is the maximum likelihood estimate, the standard derivations of the asymptotic normal distribution of T_n , can, without unreasonable modifications be used to show that

$$(11) \quad \lim_{n \rightarrow \infty} E\{L_n^*(T_n, \theta)\} = \text{asymptotic variance of } T_n.$$

We now give a proof of this conjecture. We assume that the frequency function $f(x, \theta)$ satisfies the following conditions, sufficient for asymptotic normality, as stated in Cramer's Mathematical Statistics, (1946, §.33.2). Writing f for $f(x, \theta)$.

(i) For almost all (Lebesgue measure) x the derivatives $\frac{\partial \log f}{\partial \theta}$, $\frac{\partial^2 \log f}{\partial \theta^2}$, and $\frac{\partial^3 \log f}{\partial \theta^3}$ exist for every θ belonging to a non-degenerate interval A ;

(ii) For every θ in A , we have $\frac{\partial f}{\partial \theta} < F_1(x)$, $|\frac{\partial^2 f}{\partial \theta^2}| < F_2(x)$ and $|\frac{\partial^3 \log f}{\partial \theta^3}| < H(x)$

the functions F_1 and F_2 being (Lebesgue) integrable over $(-\infty, \infty)$

while

$$\int_{-\infty}^{\infty} H(x) f(x, \theta) dx < M$$

where M is independent of θ ,

(iii) For every θ in A , the integral $\int_{-\infty}^{\infty} (\frac{\partial \log f}{\partial \theta})^2 f dx$ is finite and positive.

These conditions are sufficient for asymptotic normality of T_n . For proving our result, we assume that f satisfies the following further condition.

FURTHER CONDITION: (iv) For every θ in A , the integrals $\int_{-\infty}^{\infty} (\frac{\partial^2 \log f}{\partial \theta^2})^2 f dx$

and $\int_{-\infty}^{\infty} (H(x))^2 dx$ are finite, or in other words the random variables

$\frac{\partial^2 \log f}{\partial \theta^2}$ and $H(x)$ have finite variances.

We now use the same notation as in Cramer (1946) except that we denote the parameter by θ , instead of α and the maximum likelihood estimate by $T_n = T_n(X_1, X_2, \dots, X_n)$ instead of α^* . θ_0 denotes the unknown true value of the parameter θ , and θ_0 .

is assumed to be an interior point of A. We write f_i in place of $f(x_i, \theta)$ and use the subscript 0 to indicate that θ is to be put equal to θ_0 . Then putting

$$B_0 = \frac{1}{n} \sum_{i=1}^n \left(\frac{\partial \log f_i}{\partial \theta} \right)_0, \quad B_1 = \frac{1}{n} \sum_{i=1}^n \left(\frac{\partial^2 \log f_i}{\partial \theta^2} \right)_0$$

$$(12) \quad B_2 = \frac{1}{n} \sum_{i=1}^n H(x_i)$$

and

$$E\left(\frac{\partial^2 \log f}{\partial \theta^2}\right)_0 = -E\left(\frac{\partial \log f}{\partial \theta}\right)^2 = -k^2$$

it is shown as in Cramer (1946), that

$$(13) \quad k\sqrt{n}(T_n - \theta_0) = \frac{\frac{1}{k\sqrt{n}} \sum_{i=1}^n \left(\frac{\partial \log f}{\partial \theta} \right)_0}{-\frac{B_1}{k^2} - \frac{1}{2} \alpha B_2 (T_n - \theta_0)/k^2}$$

where $0 \leq |\alpha| < 1$.

The asymptotic normality of $(T_n - \theta)$ follows from (13).

In (13), we now put for brevity

$$u_n = k\sqrt{n} (T_n - \theta)$$

(14) and

$$v_n = -\frac{B_1}{k^2} - 1 - \frac{1}{2} \alpha B_2 (T_n - \theta_0)/k^2$$

so that the denominator in the r.h.s. of (13) is $1+v_n$. Hence from (13), and

(14)

$$u_n^2(1 + v_n)^2 = \frac{1}{k^2 n} \left[\sum_{i=1}^n \left(\frac{\partial \log f}{\partial \theta} \right)_0 \right]^2$$

so that

$$(15) \quad u_n^2 + 2u_n^2 v_n \leq \frac{1}{k^2 n} \left[\sum_{i=1}^n \left(\frac{\partial \log f}{\partial \theta} \right)_0 \right]^2$$

Let $F_n = F_n(x_1, x_2, \dots, x_n)$ denote the d.f. of the X_i , $i = 1, 2, \dots, n$. We now integrate both sides of (15), with respect to the probability measure

determined by F_n , on the subset D of the sample space R_n , given by

$$(16) \quad D = \{x: |T_n - \theta_0| \leq \delta\}$$

where $x = (x_1, x_2, \dots, x_n)$ denotes a point in R_n and δ is some positive constant, whose value shall be determined later. We thus have from (15),

$$(16) \quad \int_D u_n^2 dF_n + 2 \int_D u_n^2 v_n dF_n \leq \frac{1}{k^2} \int_D \left[\sum_{i=1}^n \left(\frac{\partial \log f_i}{\partial \theta} \right)_0 \right]^2 dF_n.$$

Now in the r.h.s. of (16), for each i , $i = 1, 2, \dots, n$,

$$E\left(\frac{\partial \log f_i}{\partial \theta}\right)_0 = 0$$

and by (12)

$$E\left(\frac{\partial \log f_i}{\partial \theta}\right)_0^2 = k^2$$

Hence since the variables x_i , $i = 1, 2, \dots, n$, are independently distributed,

$$E\left[\sum_{i=1}^n \left(\frac{\partial \log f_i}{\partial \theta}\right)_0\right]^2 = \int_{R_n} \left[\sum_{i=1}^n \left(\frac{\partial \log f_i}{\partial \theta}\right)_0\right]^2 = nk^2$$

and hence

$$(17) \quad \text{r.h.s. of (16)} \leq 1$$

Now by the assumed condition (iii) $E\{H(x)\}_0$ exists and is finite. Let

$$(18) \quad E\{H(x)\}_0 = \mu(\theta_0)$$

Then using (14) and (18)

$$(19) \quad \begin{aligned} \text{l.h.s. of (16)} &= \int_D u_n^2 dF_n - 2 \int_D u_n^2 \left(\frac{B_1}{k^2} + 1\right) dF_n \\ &\quad - \int_D u_n^2 \alpha \mu(\theta_0) \frac{(T_n - \theta_0)}{k^2} dF_n - \int_D u_n^2 \alpha [B_2 - \mu(\theta_0)] \frac{(T_n - \theta_0)}{k^2} dF_n \\ &= \text{say } g_1 + 2g_2 + g_3 + g_4 \end{aligned}$$

where g_i , $i = 1, 2, \dots, 4$ is written for brevity for the i th term in the r.h.s. of (19).

We now derive upper bounds for $|g_2|$, $|g_3|$ and $|g_4|$, by applying Schwarz' inequality and using the fact that for $x \in D$, by (14) and (16)

$$|u_n| \leq k\sqrt{n} \delta.$$

We have by Schwarz' inequality

$$(20) \quad g_2^2 \leq \int_D u_n^4 dF_n \int_D \left(\frac{B_1}{k^2} + 1\right)^2 dF_n$$

Now in (20), using (12),

$$(21) \quad \frac{B_1}{k^2} + 1 = \frac{1}{nk^2} \sum_{i=1}^n \left[\left(\frac{\partial^2 \log f_i}{\partial \theta^2} \right)_o + k^2 \right]_o$$

where by (12), for each i , $i=1, 2, \dots, n$

$$E \left[\left(\frac{\partial^2 \log f_i}{\partial \theta^2} \right)_o + k^2 \right] = 0$$

and by the assumed further condition (iv)

$$E \left[\left(\frac{\partial^2 \log f_i}{\partial \theta^2} \right)_o + k^2 \right]^2 = \sigma_1^2(\theta_o) \text{ say}$$

Hence since the x_i are distributed independently

$$\begin{aligned} E \left\{ \sum_{i=1}^n \left[\left(\frac{\partial^2 \log f_i}{\partial \theta^2} \right)_o + k^2 \right] \right\}^2 &= \int_{R_n} \left\{ \sum_{i=1}^n \left[\left(\frac{\partial^2 \log f_i}{\partial \theta^2} \right)_o + k^2 \right] \right\}^2 dF_n \\ &= n \sigma_1^2(\theta_o) \end{aligned}$$

so that,

$$(22) \quad \int_D \left\{ \sum_{i=1}^n \left[\left(\frac{\partial^2 \log f_i}{\partial \theta^2} \right)_o + k^2 \right] \right\}^2 \leq n \sigma_1^2(\theta_o)$$

Hence in (20), by (21) and (22),

$$(23) \quad \int_D \left(\frac{B_1}{k^2} + 1\right)^2 dF_n \leq \frac{\sigma_1^2(\theta_o)}{nk^4}$$

Again in the first integral in the r.h.s. of (20), since by (16) and (14)

$$u_n^2 \leq k^2 n \delta^2$$

$$(24) \quad \int_D u_n^4 dF_n \leq k^2 n \delta^2 \int_D u_n^2 dF_n = k^2 n \delta^2 \varepsilon_1$$

Combining (23) and (24) with (20), we have

$$\varepsilon_2^2 \leq \frac{\delta^2 \sigma_1^2(\theta_0)}{k^2} \varepsilon_1$$

so that

$$(25) \quad |\varepsilon_2| \leq \frac{\delta \sigma_1(\theta_0)}{k} (\varepsilon_1)^{\frac{1}{2}}$$

Next in ε_3 in (19),

$$|\alpha| \leq 1,$$

by assumed condition (ii), $|\mu(\theta_0)| \leq M$,

and by (16) $|T_n - \theta_0| \leq \delta$

and hence

$$(26) \quad |\varepsilon_3| \leq \frac{M \delta}{k^2} \int_D u_n^2 dF_n = \frac{M \delta \varepsilon_1}{k^2}$$

Lastly in ε_4 , since $|\alpha| \leq 1$ and $|T_n - \theta_0| \leq \delta$

$$(27) \quad |\varepsilon_4| \leq \frac{\delta}{k^2} \int_D u_n^2 |B_2 - \mu(\theta_0)| dF_n$$

etting

$$\varepsilon_5 = \int_D u_n^2 |B_2 - \mu(\theta_0)| dF_n$$

we again apply Schwarz' inequality, and have

$$(28) \quad \varepsilon_5^2 \leq \int_D u_n^4 dF_n \int_D [B_2 - \mu(\theta_0)]^2 dF_n$$

In the second integral in the r.h.s. of (28), by (12)

$$(29) \quad B_2 - \mu(\theta_0) = \frac{1}{n} \sum_{i=1}^n [H(x_i) - \mu(\theta_0)]$$

where for each i , $i = 1, 2, \dots, n$

$$\text{by (14)} \quad E[H(x_i) - \mu(\theta_0)] = 0$$

and by assumed further condition (iv)

$$E[H(x_i) - \mu(\theta_0)]^2 \text{ is finite} = \sigma_2^2(\theta_0) \text{ say.}$$

Hence since the x_i are distributed independently, in (29)

$$E[B_2 - \mu(\theta_0)]^2 = \frac{\sigma_2^2(\theta_0)}{n}$$

so that in (28),

$$(30) \quad \int_D [B_2 - \mu(\theta_0)]^2 dF_n \leq \frac{\sigma_2^2(\theta_0)}{n}$$

Now in the first integral in the r.h.s. of (28), since by (12) and (16)

$$u_n^2 \leq n k^2 \delta^2$$

$$(31) \quad \int_D u_n^4 dF_n \leq n k^2 \delta^2 \int_D u_n^2 dF_n = n k^2 \delta^2 g_1$$

so that combining (27), (30) and (31)

$$(32) \quad |g_4| \leq \frac{\delta^2 \sigma_2^2(\theta_0)}{k} (g_1)^{\frac{1}{2}}$$

Now in the r.h.s. of (19), obviously

$$(33) \quad g_1 + 2g_2 + g_3 + g_4 \geq g_1 - 2|g_2| - |g_3| - |g_4|$$

and hence collecting together the results in (25), (26), and (32), we have from (16), (17) and (19) using (33),

$$(34) \quad g_1 \left(1 - \frac{M \delta}{k^2}\right) - \frac{1}{g_1^{\frac{1}{2}}} \left[\frac{2\delta \sigma_1(\theta_0)}{k} + \frac{\delta^2 \sigma_2(\theta_0)}{k} \right] \leq 1$$

and denoting the coefficient of g_1 in (34) by 2κ , where $\kappa \geq 0$ we write (34)

as

$$(35) \quad g_1 \left(1 - \frac{M \delta}{k^2}\right) - 2\kappa g_1^{\frac{1}{2}} \leq 1$$

We now assume that κ is sufficiently small so that the coefficient of g_1 in the l.h.s. of (35) is positive; say,

$$(36) \quad \delta \leq \frac{k^2}{2M}$$

Then solving the quadratic in $g_1^{\frac{1}{2}}$

$$g_1 \left(1 - \frac{M \delta}{k^2}\right) - 2\kappa g_1^{\frac{1}{2}} = 1$$

(35) is seen to imply

$$\begin{aligned} g_1^{\frac{1}{2}} &\leq \frac{\kappa + \sqrt{\left\{1 - \frac{M \delta}{k^2} + \kappa^2\right\}}}{1 - \frac{M \delta}{k^2}} \\ &< \frac{\kappa + \sqrt{\left\{1 + \frac{M \delta}{k^2} + \kappa^2\right\}}}{1 - \frac{M \delta}{k^2}} \\ &< \frac{\kappa + 1 + \frac{M \delta}{2k^2} + \kappa}{1 - \frac{M \delta}{k^2}} \end{aligned}$$

so that substituting the value of κ from (34), we have

$$g_1^{\frac{1}{2}} < \frac{1}{1 - \frac{M \delta}{k^2}} \left\{ 1 + \delta \left[\frac{2 \sigma_1(\theta_0)}{k} + \frac{\delta^2 \sigma_2(\theta_0)}{k^2} + \frac{M}{2k^2} \right] \right\}$$

which using (36), can be reduced to the form

$$(37) \quad g_1 < 1 + A(\theta_0) \delta$$

where $A(\theta_0)$ is independent of δ

Returning to the loss function in (4), we now write it in the form

$$(38) \quad L_n^*(t, \theta_0) = n(t - \theta)^2 [1 + h(t, \theta_0)]$$

where by assumption, given any arbitrary number $\epsilon > 0$, we can find a δ_0 , such that

$$(39) \quad |h(t, \theta)| \leq \epsilon \text{ for all } t, \text{ such that } |t - \theta_0| \leq \delta_0$$

We now take $\delta = \min[\delta_0, \frac{k^2}{2M}]$, so that δ satisfies both (36) and (39)

Now

$$(40) \quad \begin{aligned} E\{L_n^*(T_n, \theta_0)\} &= \int_{R_n} L_n^*(T_n, \theta_0) dF_n \\ &= \int_D L_n^*(T_n, \theta_0) dF_n + \int_{R_n - D} L_n^*(T_n, \theta_0) dF_n \end{aligned}$$

D being the subset of R_n defined by (16)

Now the first integral in the r.h.s. of (40)

$$= \int_D n(T_n - \theta_0)^2 dF_n + \int_D n(T_n - \theta_0)^2 h(T_n, \theta_0) dF_n$$

which by (39)

$$\leq (1 + \epsilon) \int_D n(T_n - \theta_0)^2 dF_n$$

Hence noting the definitions of g_1 and u_n in (19) and (14)

$$(41) \quad \int_D L_n^*(T_n, \theta_0) dF_n \leq \frac{(1 + \epsilon)g_1}{k^2}$$

Then consider the second integral in the r.h.s. of (40). Here we note that since the distribution of T_n is asymptotically normal, by a well known property of the Normal frequency function (8) holds for T_n . Hence for given δ , and ϵ , by making n sufficiently large, we can make

$$(42) \quad P[|T_n - \theta_0| > \delta] = P[R_n - D] \leq \frac{\epsilon}{nC}$$

where C is the upper bound in (10). Then from (10) and (42)

$$(43) \quad \int_{R_n - D} L_n^*(T_n, \theta_0) dF_n \leq \epsilon$$

Now collecting the results in (40), (41), and (43) and using (37), we have

$$(44) \quad E\{L_n^*(T_n, \theta_0)\} = \int_{R_n} L_n^*(T_n, \theta_0) dF_n \\ \leq (1 + A(\theta_0)\delta) \frac{(1 + \epsilon)}{k^2} + \epsilon$$

for all sufficiently large n .

Since ϵ and δ can be made arbitrarily small, it follows that

$$(45) \quad \limsup_{n \rightarrow \infty} E\{L_n^*(T_n, \theta_0)\} \leq \frac{1}{k^2}$$

But $\frac{1}{k^2}$ is the asymptotic variance of T_n , and hence from (5) and (6)

$$(46) \quad \liminf_{n \rightarrow \infty} E\{L_n^*(T_n, \theta_0)\} \geq \frac{1}{k^2}$$

(45) and (46) together imply

$$(47) \quad E\{L_n^*(T_n, \theta_0)\} = \frac{1}{k^2}$$

which was to be proved.

3. Asymptotic Efficiency.

Here we incidentally point out another optimum property of a m.l.e., which is implied by a relation given in Cherno (1956), but which has a special significance in relation to superefficient estimates, which is stressed here. According to Fisher's original concept of asymptotic efficiency (A.E. for short), the A.E. of any estimate T_n is given by

$$(48) \quad \text{A. E.} = \frac{1}{\lim_{n \rightarrow \infty} \{n I(\theta) E[T_n - \theta]^2\}}$$

where $I(\theta)$ is Fisher's measure of information; evaluated at θ ,

$$(49) \quad I(\theta) = E_{\theta} \left\{ \frac{1}{f^2} \left(\frac{\partial f}{\partial \theta} \right)^2 \right\}$$

It was assumed that this A. E. has an upper bound of 1. This assumption has however turned out to be false, and in fact the A. E. in (48) has no upper bound, so that given any estimate we can construct another uniformly superior to it and there exists no most efficient estimate. The Fisherian concept of A. E. is thus void.

A superefficient estimate is one whose A. E. is not less than 1 for any θ and exceeds 1 for at least one θ . An example of such an estimate was first presented by J. L. Hodges, Jr. in 1951. The example relates to a Normal population $N(\theta, 1)$, and is

$$(50) \quad T_n = \alpha \bar{x}_n \quad \text{if} \quad |\bar{x}_n| \leq \frac{1}{n^{\frac{1}{4}}}$$

$$T_n = \bar{x}_n \quad \text{if} \quad |\bar{x}_n| > \frac{1}{n^{\frac{1}{4}}}$$

where α is some constant, such that $0 \leq |\alpha| < 1$ and \bar{x}_n is the sample mean.

$$\bar{x}_n = \frac{1}{n} \sum_{i=1}^n x_i$$

Further examples of superefficient estimates were later given by Le Cam (1953) who constructed an example where the set of superefficiency, i.e. the set of values of θ for which the A. E. exceeds 1, is non-denumerable and everywhere dense. It was also proved by him that the set of superefficiency must necessarily be of Lebesgue measure zero.

It should be noted here, that though the A. E. of the superefficient estimate T_n in (48) is for all θ higher than that of m.l.e. \bar{x}_n , T_n is not 'superior' to \bar{x}_n , even if we take the M.S.E. (mean squared error) as the sole criterion. While T_n has a lower M.S.E. at $\theta = 0$, for every n , however large, there exist values of θ (in fact an interval of values) in which \bar{x}_n has a lower M.S.E. The observation made sometimes, that according to a 'behaviourist viewpoint' the superefficient estimate T_n has to be preferred to \bar{x}_n is thus not correct. As pointed out by Le Cam (1953) the same thing occurs in the case of all other superefficient estimates.

The author considers that this reveals a defect in the definition (48) as the possession of a higher A. E. does not imply the possession of a higher degree of some desirable property. The defect in this definition (48) arises from the fact that it takes into consideration the performance of the estimate T_n for each value of n at some single point $\theta = \theta_0$. The true value of θ is however not known, though as n increases we can locate θ more and more closely with a given degree confidence. This suggests that a revised definition of A. E. should take into account the performance of T_n , not at a single point θ_0 but in some neighbourhood of it, With these considerations a modified definition of A. E. is proposed below.

Let c_n be a sequence of positive numbers such that

$$(51) \quad \begin{aligned} c_n &\rightarrow 0 \\ \sqrt{n} c_n &\rightarrow \infty \end{aligned}$$

Then the suggested revised definition is

$$(52) \quad \text{A.E.} = \liminf_{n \rightarrow \infty} \frac{1}{\sup_{\theta_0 - c_n < \theta < \theta_0 + c_n} [n I(\theta) E_{\theta}(T_n - \theta)^2]}$$

The following result is proved in Chernoff(1956, Theorem 1)

$$(53) \quad \lim_{k \rightarrow \infty} \liminf_{n \rightarrow \infty} \sup_{-\frac{k}{4\sqrt{n}} < \theta < \frac{k}{4\sqrt{n}}} \{ n I(\theta) E_{\theta}(\min[(T_n - \theta)^2, \frac{k^2}{n}]) \} \geq 1$$

From the proof of the theorem, it is seen that the following conditions are assumed,

(a) that the frequency function $f(x, \theta)$ and the estimate T_n , satisfy the 'regularity' conditions sufficient for the Cramer-Rao inequality, such as those given by Wolfowitz

(b) $I(\theta)$ is bounded away from zero in some neighbourhood of $\theta = 0$.

For (52) we now replace condition (b) by the condition

(c) $I(\theta)$ bounded away from zero in some neighborhood of every point θ_0 , in the range of values assumed by θ .

It is then easily seen to be a consequence of (53), that the A. E. defined by (52), has an upper bound of 1. It is further seen that this upper bound is attained for a m.l.e. while for the superefficient estimate T_n the A. E. by the revised definition is nil.

Acknowledgement

The relation given in (53) was pointed out to me by a referee of the Annals in connection with another paper. I have also to thank Mrs. Kay Herring for doing the typing work neatly and speedily.
